Abstract. Let E be the elliptic curve 37C in Cremona's table with the equation

$$E : y^2 + y = x^3 + x^2 - 23x - 50.$$

We show that for at least 40% of the positive fundamental discriminants D and at least 24% of the negative fundamental discriminants D, $\mathrm{Ord}_{s=1}L(s, E_D) = 1$.

Mathematics Subject Classification (2000). 11M, 11R.

Key words. rank, quadratic twist, elliptic curve.

1 Introduction and statement of result

Let $E : y^2 = x^3 + ax + b$ be an elliptic curve over $\mathbb{Q}$ and let $L(s, E) = \sum_{n=1}^{\infty} a(n)n^{-s}$ be its Hasse-Weil L-function. Let D be the fundamental discriminant of the quadratic field $\mathbb{Q}(\sqrt{D})$ and let $\chi_D = (\frac{D}{\cdot})$ denote the usual Kronecker character. Then the Hasse-Weil L-function of the quadratic twist $E_D : Dy^2 = x^3 + ax + b$ of E is the twisted L-function $L(s, E_D) = \sum_{n=1}^{\infty} \chi_D(n)a(n)n^{-s}$. Goldfeld [4] conjectured that

$$\sum_{|D|<X} \mathrm{Ord}_{s=1}L(s, E_D) \sim \frac{1}{2} \sum_{|D|<X} 1. \tag{1}$$

*This work was supported by grant No. R08-2003-000-10243-0 from the Basic Research Program of the Korea Science & Engineering Foundation

This conjecture implies the weaker statement

$$\sharp\{|D| < X|\ \mathrm{Ord}_{s=1}L(s, E_D) = r\} \gg X, \tag{2}$$

where $r = 0$ or 1. For the case $r = 0$, there are infinitely many special elliptic curves E satisfying the weaker statement (cf. [5] [12]) and the best known general result is due to Ono and Skinner [9], who showed that

$$\sharp\{|D| < X|\ \mathrm{Ord}_{s=1}L(s, E_D) = 0\} \gg X/\ \log X.$$

For the case $r = 1$, the best known general result is following [10];

$$\sharp\{|D| < X|\ \mathrm{Ord}_{s=1}L(s, E_D) = 1\} \gg_\epsilon X^{1-\epsilon}.$$

However only one special elliptic curve $E = X_0(19)$ satisfying the weaker statement (2) is known due to Vatsal [11]. We note that $X_0(19)$ is the unique modular curve $X_0(N)$ such that the genus of $X_0(N)$ is 1, N is prime, and 3 divides the number $n = (N-1)/m$ where $m = \gcd(12, N-1)$. The aim of this note is to provide another example satisfying the weaker statement (2) for the case $r = 1$ and give an estimate of the lower bound which give an evidence of Goldfeld conjecture (1).

Theorem 1.1 *Let E be the elliptic curve 37C in Cremona's table with the equation*

$$E : y^2 + y = x^3 + x^2 - 23x - 50.$$

Then for at least 40% of the positive fundamental discriminants D and at least 24% of the negative fundamental discriminants D, $\mathrm{Ord}_{s=1}L(s, E_D) = 1$.

Remark. Let E be the elliptic curve 37C and $E_D(\mathbb{Q})$ be the Mordell-Weil group of E_D over $\mathbb{Q}$. Then Theorem 1.1 together with a celebrated theorem of Kolybagin implies that for at least 40% of the positive fundamental discriminants D and at least 24% of the negative fundamental discriminants D, the rank of $E_D(\mathbb{Q})$ is equal to 1.

To prove Theorem 1.1, like [11], we will use the result of Gross [2] on the non-triviality of Heegner points of Eisenstein curves, the results of Davenport-Heilbronn [1] and Nakagawa-Horie [8] on the 3-rank of the class groups of quadratic fields, and Gross-Zagier theorem [3] on Heegner points and derivatives of L-series. A new ingredient in this note is to use the fact that $X_0(37)$ is the unique modular curve $X_0(N)$ such that N is prime, and 3 divides the number $n = (N-1)/m$, and the minus part of its Jacobian is an elliptic curve.

2 Preliminaries

First we recall the result of Gross [2] on the non-triviality of Heegner points of Eisenstein curves. Let N be a prime number, $m = \gcd(12, N-1)$, and p be an odd prime factor of the number $n = (N-1)/m$. Let X be the modular curve $X_0(N)$ and J be the Jacobian of X. Let K be an imaginary quadratic fields of discriminant D_K in which the prime $(N) = \mathbf{n} \cdot \bar{\mathbf{n}}$ splits completely. Let w_K denote the number of roots of unity in K.

Theorem 2.1 *(Gross) Let χ be the quadratic ring class characters of K of conductor c corresponding to the factorization*

$$c^2 \cdot D_K = d \cdot d',$$

where $d > 0$ is the fundamental discriminant of real quadratic field k and $d' < 0$ is the fundamental discriminant of imaginary quadratic field k'. Let $L = kk'$ and y_χ be the Heegner divisor in $J(L)$. Let h and h' be the class numbers of k and k' respectively. Assume $\chi(\mathbf{n}) = -1$ and $\mathrm{ord}_p(hh') < \mathrm{ord}_p(n)$. Then the projection $y_\chi^{(p)}$ of y_χ into the p-Eisenstein quotient $J^{(p)}(L)$ of $J(L)$ has infinite order.

Theorem 2.2 *(Gross) Let $\chi = 1$ and y_χ be the Heegner divisor in $J(K)$. Let $A = \mathcal{O}_K[N^{-1}]$ and h_A be the class number of A. Assume $(p, w_K) = 1$ and $\mathrm{ord}_p(h_A) < \mathrm{ord}_p(n)$. Then the projection $y_\chi^{(p)}$ of y_χ into the p-Eisenstein quotient $J^{(p)}(K)$ of $J(K)$ has infinite order.*

Now we recall the result of Nakagawa and Horie [8] which is a refinement of the result of Davenport and Heilbronn [1]. Let m and N be two positive integers satisfying the following condition:

> $(*)$ If an odd prime number p is a common divisor of m and N, then p^2 divides N but not m. Further if N is even, then (i) 4 divides N and $m \equiv 1 \pmod 4$, or (ii) 16 divides N and $m \equiv 8$ or $12 \pmod{16}$.

For any positive real number $X > 0$, we denote by $S_+(X)$ the set of positive fundamental discriminants $D < X$ and by $S_-(X)$ the set of negative fundamental discriminants $D > -X$, and put

$$S_+(X, m, N) := \{D \in S_+(X) \mid D \equiv m \,(\mathrm{mod\ N})\},$$
$$S_-(X, m, N) := \{D \in S_-(X) \mid D \equiv m \,(\mathrm{mod\ N})\}.$$

Theorem 2.3 *(Nakagawa and Horie) Let D be a fundamental discriminant and $r_3(D)$ be the 3-rank of the quadratic field $\mathbb{Q}(\sqrt{D})$. Then for any two positive integers m, N satisfying $(*)$,*

$$\lim_{X\to\infty} \sum_{D\in S_+(X,m,N)} 3^{r_3(D)} / \sum_{D\in S_+(X,m,N)} 1 = \frac{4}{3}$$

and

$$\lim_{X\to\infty} \sum_{D\in S_-(X,m,N)} 3^{r_3(D)} / \sum_{D\in S_-(X,m,N)} 1 = 2.$$

From Theorem 2.3 and the following fact

$$\begin{aligned} &\sum_{\substack{D\in S_\pm(X,m,N)\\ r_3(D)=0}} 3^{r_3(D)} + 3\Big(\sum_{D\in S_\pm(X,m,N)} 1 - \sum_{\substack{D\in S_\pm(X,m,N)\\ r_3(D)=0}} 3^{r_3(D)}\Big) \\ \le &\sum_{D\in S_\pm(X,m,N)} 3^{r_3(D)}, \end{aligned}$$

we can easily obtain the following lemma.

Lemma 2.4 *Let D be a fundamental discriminant and $h(D)$ the class number of the quadratic field $\mathbb{Q}(\sqrt{D})$. Then for any two positive integers m, N satisfying $(*)$,*

$$\liminf_{X\to\infty} \frac{\sharp\{D \in S_+(X,m,N) \mid h(D) \not\equiv 0 \ (mod\ 3)\}}{\sharp S_+(X,m,N)} \ge \frac{5}{6}$$

and

$$\liminf_{X\to\infty} \frac{\sharp\{D \in S_-(X,m,N) \mid h(D) \not\equiv 0 \ (mod\ 3)\}}{\sharp S_-(X,m,N)} \ge \frac{1}{2}.$$

3 Proof of Theorem 1.1

Let $N = 37$. Then $m = 12$ and $n = p = 3$. In this case $X = X_0(37)$ is the modular curve with genus 2. Decomposing $J = J_0(37)$ by means of the canonical involution w, we may consider the exact sequence

$$0 \to J_+ \to J \to J^- \to 0,$$

where $J_+ = (1+w)J$. We note that $\dim J_+ = \dim J^- = 1$ (See [6], Table in Introduction).

Proposition 3.1 *J^- is the elliptic curve 37C in Cremona's table with the equation*

$$E : y^2 + y = x^3 + x^2 - 23x - 50.$$

Proof: See [7], Proposition 1 in §5.

□

Let $\tilde{J}$ be the Eisenstein quotient of J. We know that $\tilde{J}$ factors through J^- and the p-Eisenstein quotient $J^{(p)}$ of J is a quotient of $\tilde{J}$ (See [6], chap. II (10.4) and chap. II (17.10)). Thus we have the following proposition.

Proposition 3.2 *$J^{(p)}$ is a quotient of $J^- = E$.*

Proposition 3.3 *Let k be a real quadratic field where the prime 37 is inert. If the class number h of k is prime to 3, then the projection of y_χ into $E(k)(= J^-(k))$ has infinite order.*

Proof: Let k be a real quadratic field of discriminant d where 37 is inert and whose class number h of k is prime to 3. Let k' be the imaginary quadratic field $\mathbb{Q}(\sqrt{-2})$ of discriminant -8. Note that 37 is inert in k' and the class number h' of k' is equal to 1. Let K be the third field contained in the biquadratic extension $L = kk'$. Then K is imaginary and 37 splits in K. Let D_K be the discriminant of K and χ be the quadratic ring class characters of K of conductor c corresponding to the factoring of $c^2 \cdot D_K = d \cdot (-8)$. Then from Theorem 2.1, we know that $y_\chi^{(p)}$ has infinite order in $J^{(p)}(L)$. Since $J^{(p)}$ is a quotient of $J^- = E$ by Proposition 3.2, the projection of y_χ to $E(L)$ has infinite order. We note that $E(L) = E(k) \oplus E(k')$ and $E(k') = E(\mathbb{Q}) = \mathbb{Z}/3\mathbb{Z}$. Thus the projection of y_χ to $E(k)$ should have infinite order. □

Proposition 3.4 *Let $K(\neq \mathbb{Q}(\sqrt{-3}))$ be an imaginary quadratic field where the prime 37 is split. If the class number of h of K is prime to 3, then the projection of y_χ into $E(K)(= J^-(K))$ has infinite order.*

Proof: Let K be an imaginary quadratic field where 37 is split and whose class number h of K is prime to 3. In this case, we note that h_A is simply the quotient of h_K by the order of $\mathbf{n}$ in the class group of K. Then from Theorem 2.2, we have that $y_\chi^{(p)}$ has infinite order in $J^{(p)}(L)$. Since $J^{(p)}$ factors through $J^- = E$ by Proposition 3.2, the projection of y_χ to $E(K)$ should have infinite order. □

Proof of Theorem 1.1: First we compute the number of quadratic fields k and K in Proposition 3.3 and 3.4. By a well-known method in analytic number theory we have the following estimate on $S_\pm(X, m, N)$. (See [8], Proposition 2.)

$$\sharp S_+(X, m, N) \sim \sharp S_-(X, m, N) \sim \frac{3X}{\pi^2 \varphi(N)} \prod_{p|N} \frac{q}{p+1} \qquad (X \to \infty),$$

where $q = 4$ or p according as $p = 2$ or not. Thus from Lemma 2.4, we obtain the following desired estimates.

$$\liminf_{X\to\infty} \frac{\sharp\{D \in S_+(X) \,|\, h(D) \not\equiv 0 \,(\mathrm{mod}\ 3) \quad \text{and} \ (\frac{D}{37}) = -1\}}{\sharp S_+(X)} \geq \frac{5}{6} \cdot \frac{18}{37} \simeq 0.405,$$

$$\liminf_{X\to\infty} \frac{\sharp\{D \in S_-(X) \,|\, h(D) \not\equiv 0 \,(\mathrm{mod}\ 3) \quad \text{and} \ (\frac{D}{37}) = 1\}}{\sharp S_-(X)} \geq \frac{1}{2} \cdot \frac{18}{37} \simeq 0.243.$$

Finally Theorem 1.1 follows from Proposition 3.3, Proposition 3.4, and the Gross-Zagier Theorem [3] on Heegner points and derivatives of L-series. □

Remark. Similarly we can obtain the following.

Let E be the elliptic curve $X_0(19)$ in [11]. Then for at least 39% of the positive fundamental discriminants D and at least 23% of the negative fundamental discriminants D, $\mathrm{Ord}_{s=1} L(s, E_D) = 1$.
